Data-Parallel Execution using SIMD Instructions
Single Instruction Multiple Data

- data parallelism exposed by the instruction set
- CPU register holds multiple fixed-size values (e.g., 4 times 32-bit)
- instructions (e.g., addition) are performed on two such registers (e.g., executing 4 additions in one instruction)

\[
\begin{array}{cccc}
4 & 2 & 1 & 7 \\
3 & 1 & 6 & 2 \\
\end{array}
\]

\[+
\]

\[
\begin{array}{cccc}
7 & 3 & 7 & 9 \\
\end{array}
\]
**AVX-512**

- available on Skylake server CPUs
- 32 512-bit registers: ZMM0 to ZMM31
- can be interpreted as
  - 64 8-bit integers
  - 32 16-bit integers
  - 16 32-bit integers
  - 8 64-bit integers
  - 16 32-bit floats
  - 8 64-bit floats
- extensive and fairly orthogonal set of operations
- Skylake server CPUs have 2 AVX-512 processing units and can therefore process 128 bytes per cycle
- important subsets: AVX-512F (foundation), AVX-512BW (byte, word), AVX-512DQ (doubleword and quadword instructions), AVX-512CD (lzcnt and conflict detection)
Auto-Vectorization

- compilers can sometimes transform serial code into SIMD code
- this does not work for complicated code and is quite unpredictable (one compiler may work, another may not)
Intrinsics

- Intrinsics provide an interface to SIMD instructions without writing assembly code.
- ZMM registers are represented as special data types:
  - __m512i (all integer types, width is specified by operations)
  - __m512 (32-bit floats)
  - __m512d (64-bit floats)
- Operations look like C functions, e.g., add 16 32-bit integers:
  __m512i _mm512_add_epi32(__m512i a, __m512i b)
- Compiler performs register allocation.
Getting Data To/From Registers

- aligned load (memory location has to be 64-byte aligned):
  
  ```c
  __m512i _mm512_load_si512 (void const* mem_addr)
  ```

- unaligned load (slightly slower):
  
  ```c
  __m512i _mm512_loadu_si512 (void const* mem_addr)
  ```

- broadcast a single value (available for different widths):
  
  ```c
  __m512i _mm512_set1_epi32 (int a)
  ```

- there is no instruction for loading a 64-byte constant into a register (must happen through memory); however, there is a convenient (but slow) intrinsic for that:
  
  ```c
  __m512i _mm512_set_epi32(int e15, ..., int e0)
  ```
  (arguments can also be specified in reverse: *_setr_*)

- store:
  
  ```c
  void _mm512_store_epi32 (void* mem_addr, __m512i a)
  ```
Arithmetic Operations

- addition/subtraction: add, sub
- multiplication (truncated): mullo (16, 32, or 64 bit input, output size same as input)
- saturated addition/subtraction: adds, subs (stays at extremum instead of wrapping, only 8 and 16 bits)
- absolute value: abs
- extrema: min/max
- multiplication (full precision): mul (only 32 bit input, produces 64 bit output)
- some of these are also available as unsigned variants (epu suffix)
- no integer division/modulo\(^1\)
- no overflow detection

\(^1\)division by power of 2 can be emulated using shift, division by constant can sometimes be implemented using multiplication/shifting/addition
Intrinsics Example

```c
alignas(64) int in[1024];
void simpleMultiplication() {
    __m512i three = _mm512_set1_epi32(3);
    for (int i=0; i<1024; i+=16) {
        __m512i x = _mm512_load_si512(in + i);
        __m512i y = _mm512_mullo_epi32(x, three);
        _mm512_store_epi32(in + i, y); }
}
```

```
xor    eax, eax
vmovups zmm0, ZMMWORD PTR CONST.0[rip]

.LOOP:
vpmulld zmm1, zmm0, ZMMWORD PTR [in+rax*4]
vmovups ZMMWORD PTR [in+rax*4], zmm1
add     rax, 16
cmp     rax, 1024
jl      .LOOP
ret

.CONST.0: .long 0x00000003,0x00000003,...
```
Logical and Bitwise Operations

- logical: and, andnot, or, xor
- rotate left (right) by same value: rol (ror)
- rotate left (right) by different values: rolv (rorv)
- shift\(^2\) left (right) by same value: slli (srli)
- shift left (right) by different values: sllv (srlv)
- convert different sizes (zero/sign-extend, truncate): cvt
  - 32 to 64: \_\_m512i \_\_mm512_cvtepi32_epi64 (\_\_m256i a) (sign extend)
  - 32 to 64: \_\_m512i \_\_mm512_cvtepu32_epi64 (\_\_m256i a) (zero extend)
  - 64 to 32: \_\_m256i \_\_mm512_cvtepi64_epi32 (\_\_m512i a) (truncate)
- count leading zeros: lzcnt

\(^2\)8-bit shifts are missing
Comparisons

- compare 32-bit integers:
  \[
  \text{__mmask16 } \_\text{mm512\_cmpOP\_epi32\_mask (}_\_\text{m512i } a, \_\text{m512i } b)
  \]

- OP is one of (eq, ge, gt, le, lt, neq)

- comparisons may also take a mask as input, which is equivalent to performing AND on the masks

- assumes signed integers\(^3\)

- result is a bitmap stored in a special “opmask” register (K1-K7) and is available as special data type (\_\text{mmask8} to \_\text{mmask64})

\(^3\)to compare unsigned integers, flip the most significant bit of inputs (using xor)
Data-Parallel Execution using SIMD Instructions

Masking

Operations on Masks

- operations on masks: kand, knand, knot, kor, kxnor, kxor
- __mmask16 _kand (__mmask16 a, __mmask16 b)
- masks are automatically converted to integers
- to count number of bit set to 1: __builtin_popcount(mask)
Zero Masking

- selectively ignore some of the SIMD lanes (using a bitmap)
- almost all operations support masking
- add elements, but set those not selected by mask to zero:
  \[ \text{__m512i } \_\text{mm512_maskz_add_epi32 (\_\text{mmask16 } k, \_\text{m512i } a, \_\text{m512i } b)} \]

\[
\begin{array}{cccc}
4 & 2 & 1 & 7 \\
+ & k=0101 \\
3 & 1 & 6 & 2 \\
\end{array}
\]

\[=\]

\[
\begin{array}{cccc}
0 & 3 & 0 & 9 \\
\end{array}
\]
Masking with Merging/Blending

- blend new result with previous result ("merge"):
  \[
  \text{__m512i } \text{_mm512_mask_add_epi32 (__m512i } \text{ src, __mmask16 k, __m512i a, __m512i b)}
  \]

\[
\begin{array}{cccc}
\text{src} & 5 & 2 & 2 & 7 \\
\text{a} & 5 & 2 & 2 & 7 \\
+ & k=0101 & & \\
\text{b} & 3 & 1 & 6 & 2 \\
\hline
\text{=} & & & \\
\text{5} & 3 & 2 & 9 \\
\end{array}
\]

- there are also blending only instructions:
  \[
  \text{__m512i } \text{_mm512_mask_blend_epi32 (__mmask16 k, __m512i a, __m512i b)}
  \]
Masking Example

```assembly
maskedArithmetic():
xor eax, eax
vmovups zmm2, ZMMWORD PTR .CONST.0[rip]
vmovups zmm1, ZMMWORD PTR .CONST.1[rip]
vmovups zmm0, ZMMWORD PTR .CONST.2[rip]
.LOOP: vmovups zmm3, ZMMWORD PTR [array+rax*4]
  vpcmpgtd k1, zmm2, zmm3
  vmovdqa32 zmm4{k1}{z}, zmm0
  vpmulld zmm5, zmm3, zmm1
  vpadd d zmm5{k1}, zmm3, zmm4
  vmovdqu32 ZMMWORD PTR [array+rax*4], zmm5
  add rax, 16
  cmp rax, 1024
  jb .LOOP
ret
.CONST.0: .long 0x00000009,0x00000009,...
.CONST.1: .long 0x00000007,0x00000007,...
.CONST.2: .long 0x00000003,0x00000003,...
```
Compress and Expand

- compress: `__m512i _mm512_maskz_compress_epi32(__mmask16 k, __m512i a)`
- expand: `__m512i _mm512_maskz_expand_epi32(__mmask16 k, __m512i a)`
- also to memory: `compressstoreu`
- and from memory: `expandloadu`
Selection Example

```c
uint32_t scalar(int32_t* in, int32_t inCount, int32_t x, int32_t* out) {
    uint32_t outPos = 0;
    for (int32_t i=0; i<inCount; i++)
        if (in[i] < x)
            out[outPos++] = i;
    return outPos; }

uint32_t SIMD(int32_t* in, int32_t inCount, int32_t x, int32_t* out) {
    uint32_t outPos = 0;
    __m512i cmp = _mm512_set1_epi32(x); __m512i sixteen = _mm512_set1_epi32(16);
    __m512i indexes = _mm512_setr_epi32(0,1,2,3,4,5,6,7,8,9,10,11,12,13,14,15);
    for (int32_t i=0; i<inCount; i+=16) {
        __m512i inV = _mm512_loadu_si512(in + i);
        __mmask16 mask = _mm512_cmplt_epi32_mask(inV, cmp);
        _mm512_mask_compressstoreu_epi32(out + outPos, mask, indexes);
        uint32_t count = __builtin_popcount (mask);
        indexes = _mm512_add_epi32(indexes, sixteen);
    }
    return outPos; }
```
Permute

• permute\(^4\) (also called shuffle) a using the corresponding index in idx:
  \[
  \_\_m512i \_\_mm512_permutexvar_epi32 (\_\_m512i idx, \_\_m512i a)
  \]
• a bit of a misnomer, is not just shuffle or permute but can replicate elements
• very powerful, can, e.g., be used to implement small, in-register lookup tables

<table>
<thead>
<tr>
<th>a</th>
<th>4</th>
<th>2</th>
<th>1</th>
<th>7</th>
</tr>
</thead>
<tbody>
<tr>
<td>idx</td>
<td>1</td>
<td>0</td>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>4</td>
<td>7</td>
<td>4</td>
</tr>
</tbody>
</table>

\(^4\text{not available for 8-bit values}\)
Gather (1)

- perform multiple loads and store results in register
Gather (2)

- load 16 32-bit integers using 32-bit indices:
  \[ \text{\_m512i \_mm512\_i32gather\_epi32 (\_m512i vindex, void const* base_addr, int scale)} \]

- load 8 64-bit integers using 64-bit indices:
  \[ \text{\_m512i \_mm512\_i64gather\_epi64 (\_m512i vindex, void const* base_addr, int scale)} \]

- load 16 8-bit or 16-bit values (zero or sign extended):
  \[ \text{\_m512i \_mm512\_i32extgather\_epi32 (\_m512i index, void const* mv, _MM_UPCONV\_EPI32\_ENUM conv, int scale, int hint)} \]

- indices are multiplied by scale, which must be 1, 2, 4 or 8
- gathering 8 elements performs 8 loads (using the 2 load units)
- is not necessarily faster than individual loads (unless one needs the result in SIMD register anyway)
Scatter

- store 16 32-bit integers using 32-bit indices:
  
  ```c
  void _mm512_i32scatter_epi32 (void* base_addr, __m512i vindex, __m512i a, int scale)
  ```

- store 8 64-bit integers using 64-bit indices:
  
  ```c
  void _mm512_i64scatter_epi64 (void* base_addr, __m512i vindex, __m512i a, int scale)
  ```
Conflict Detection

- problem: during a scatter, when multiple indices have the same value, bad things can happen
- test each element for equality with all other elements\(^5\):
  \[
  \_\_m512i \text{ mm512_conflict_epi32 (}\_\_m512i \text{ a)}
  \]

\(^5\)only available for 32-bit and 64-bit values
Conflict Detection With Masking

- conflict detection instructions also support masking
- however, an element selected by the mask is still compared with all other elements (even ones that are not selected by the mask)
- possible solution: set elements one wants to ignore to a value that does not occur in the vector, mask
Cross-Lane Operations, Reductions

- often one would like to perform operations *across* lanes
- except for some exceptions (e.g., permute), this cannot be done efficiently
- horizontally vectorized operations and violate the SIMD paradigm (i.e., are slow)
- for example, there is an intrinsic for adding register values:
  ```c
  int __mm512_reduce_add_epi32 (__m512i a)
  ```
- but (if supported by the compiler), it is translated to multiple SIMD instructions (by the compiler) and is therefore less efficient than __mm512_add_epi32
Other Useful Instructions

- most SSE/AVX256 instructions are strictly worse than their AVX-512 equivalents (if your CPU supports it)
- SSE4.2 is an exception, provides CRC and parallel string comparisons
- allows comparing two 16-byte chunks, e.g., to find out whether (and where) a string contains a set of characters
- very flexible: len/zero-terminated strings, any/substring search, bitmask/index result, etc.
- tool for finding the correct settings: http://halobates.de/pcmpstr-js/pcmp.html
- BMI instruction set is another exception
  - extract bits indicated by mask from 64-bit value a:
    - `uint64_t _pext_u64 (uint64_t a, uint64_t mask)`
    - `uint64_t _pdep_u64 (uint64_t a, uint64_t mask)`
  - like compress/expand, but at bit level
Other Optimization Issues

- C++ aliasing semantics (__restrict__)
- vectorization vs. guaranteed floating point semantics: (-ffast-math)
