Introduction to the Relational Model and SQL

After completing this chapter, you should be able to:

▷ explain basic notions of the relational model:
  • table/relation, row/tuple, column/attribute, column value/attribute value,
▷ explain the meaning of keys and foreign keys,
▷ write simple SQL queries (queries against a single table).
Introduction to the Relational Model and SQL

Overview

1. The Relational Model, Example Database
2. Simple SQL Queries
3. Historical Remarks
The relational model structures data in tabular form, i.e., a relational database is a set of named tables.

<table>
<thead>
<tr>
<th>A relational database schema defines:</th>
</tr>
</thead>
<tbody>
<tr>
<td>① <strong>Names of tables</strong> in the database,</td>
</tr>
<tr>
<td>② the <strong>columns of each table</strong>, <em>i.e.</em>, the <strong>column name</strong> and the <strong>data types</strong> of the column entries,</td>
</tr>
<tr>
<td>③ <strong>integrity constraints</strong>, <em>i.e.</em>, conditions that data entered into the tables is required to satisfy.</td>
</tr>
</tbody>
</table>
The Relational Model (2)

- **Example:** Assume a database maintaining information about a small real-world subset: a company’s departments and employees.

- Two tables:
  - EMP: information about employees.
  - DEPT: information about departments.

<table>
<thead>
<tr>
<th>DEPTNO</th>
<th>DNAME</th>
<th>LOC</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
<tr>
<td>20</td>
<td>RESEARCH</td>
<td>DALLAS</td>
</tr>
<tr>
<td>30</td>
<td>SALES</td>
<td>CHICAGO</td>
</tr>
<tr>
<td>40</td>
<td>OPERATIONS</td>
<td>BOSTON</td>
</tr>
</tbody>
</table>
The three columns of table DEPT have the following data types:

- **DEPTNO** has data type NUMERIC(2), i.e., the column can hold two-digit integer entries \(-99\ldots99\).
  An integrity constraint can be used to exclude negative department numbers.

- **DNAME** has type VARCHAR(14), i.e., the entries are character strings of variable length of up to 14 characters.

- **LOC** has type VARCHAR(13).
• A relational database state (instance of a given schema) defines a set of rows for each table.

• In the now current state, table DEPT has four rows.

• The relational model does not define any particular order of the rows (e.g., first row, second row).

  Rows can be sorted for output, though.

• Each row specifies values for each column of the table.
A relational table

Table Name

Column

Row

Table Entry
Summary (2)

- A more theoretically inclined person would use the following equivalent terminology:

- Table $\equiv$ relation

  Formally, a table is a subset of the Cartesian product of the domains of the column data types, i.e., a relation in the mathematical sense.

  **Example:** Cartesian coordinates are $(X, Y)$-tuples of real numbers, i.e., elements of $\mathbb{R} \times \mathbb{R}$. The relation $<$ defines a subset of $\mathbb{R} \times \mathbb{R}$, e.g., $(1, 2)$ is contained in $<$, while $(2, 1)$ is not.

  In an RDBMS, relations are always finite and may involve more than two columns.

- Row $\equiv$ tuple
- Column $\equiv$ attribute
“Old-style” practitioners might equivalently say:

- **Row** \(\equiv\) **record**

  A table row (or tuple) is basically the same as a **record** in Pascal or **struct** in C: it has several named components. However, the storage structure of a tuple in external memory (disk) does not necessarily match the layout of a record in main memory.

- **Column** \(\equiv\) **field**

- **Table entry** \(\equiv\) **field value**

- **Table** \(\equiv\) **file**
The column `DEPTNO` is declared as the **key** of table `DEPT`.

**Relational Keys**

A key always **uniquely identifies a single row** in its associated table.

Table `DEPT`, for example, already contains a row with key `DEPTNO = 10`.

If one tries to add another row with the same value 10 for `DEPTNO`, the DBMS responds with an error.
Keys (2)

- Keys are an example of **constraints**: conditions that the table contents (database state) must satisfy *in addition* to the basic structure prescribed by the columns.

- Constraints are declared as part of the database schema.

- More than one key can be declared for a table

---

**More keys?**

One could, for example, discuss whether DNAME should also be a key (in addition to DEPTNO already being a key). This would exclude the possibility that there can ever be two or more departments of the same name.

- Keys and other constraints are treated in Chapter 2.
Table EMP (data about employees) with the following columns:

- **EMPNO**: A unique number for every employee
- **ENAME**: Employee name
- **JOB**: Employee position (e.g., ENGINEER)
- **MGR**: Direct supervisor of this employee
- **HIREDATE**: Employee hire date
- **SAL**: Employee salary
- **COMM**: Commission (only for salespeople)
- **DEPTNO**: Department of employee
Another Example Table (2)

Table EMP

<table>
<thead>
<tr>

<td>20</td>
</tr>
</tbody>
</table>
• **Physical pointers (memory addresses) are unknown** to the relational model.

• However, the relational model provides a kind of “**logical pointer.**”

  ▶ For example, the column DEPTNO in table EMP **refers to** column DEPTNO in table DEPT.

• Since DEPTNO is declared as a key in table DEPT, a department number uniquely identifies a single row of DEPT.

• A value for DEPTNO (in table EMP) can be seen as a “logical address” of a row in table DEPT.
Foreign Keys (2)

• By including a department number in table EMP, each row in EMP “points to” a single row in table DEPT.

• It is important for the integrity of the database, that the department numbers in EMP in fact occur in DEPT.

“Dangling pointers”

If a row in table EMP contains a DEPTNO value of 70, the reference “dangles.”

A DBMS, however, does not crash as would be the case with real physical pointers (memory addresses). In SQL, references are followed by comparing column values. Nevertheless, such a column entry is a kind of error and should be avoided. This is the purpose of foreign keys.
• The relational model permits to declare column DEPTNO as a **foreign key** that references table DEPT.

Then the DBMS will refuse

- an insertion into table EMP with a value for DEPTNO that **does not appear** in DEPT,
- a deletion of a row in DEPT that is **still referenced** by a row in EMP,
- corresponding updates (changes) of DEPTNO values.

---

[^a]: It might be reasonable to recursively delete all employees of that department, too (cascading delete).
• Table EMP also contains a second foreign key:
  Column MGR contains the employee number of the employee’s direct supervisor.

• This shows that
  ▶ it is possible that a foreign key refer to another row in the same table (or even the same row),
  ▶ the foreign key column and referenced key may have different names (here: MGR and EMPNO).
Null Values

- The relational model allows column entries to remain empty (i.e., the column/row contains a null value).

- For example, in table EMP:
  1. only salespeople have a commission,
  2. the company president has no supervisor.

- When a table schema is declared, we may specify for each column whether null values are accepted or not.

- Null values are treated specially in comparisons.
Overview

1. The Relational Model, Example Database
2. Simple SQL Queries
3. Historical Remarks
Simple SQL Queries (1)

- Simple SQL queries have the following syntactic form:

  SELECT · · · FROM · · · WHERE · · ·

  ▶ After FROM: comma-separated list of **table names** from which to extract data.

  ▶ After WHERE: specify predicate (Boolean expression, \textit{true/false}) which selected **rows** are required to satisfy. A missing WHERE-clause is equivalent to WHERE TRUE.

  ▶ After SELECT: define which **columns** appear in the result table.

  Note: SELECT * selects all columns
Show the entire department table (all rows, all columns)

SELECT * FROM DEPT

• Result:

<table>
<thead>
<tr>
<th>DEPTNO</th>
<th>DNAME</th>
<th>LOC</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>ACCOUNTING</td>
<td>NEW YORK</td>
</tr>
<tr>
<td>20</td>
<td>RESEARCH</td>
<td>DALLAS</td>
</tr>
<tr>
<td>30</td>
<td>SALES</td>
<td>CHICAGO</td>
</tr>
<tr>
<td>40</td>
<td>OPERATIONS</td>
<td>BOSTON</td>
</tr>
</tbody>
</table>

• Equivalent formulation:

SELECT DEPTNO, DNAME, LOC FROM DEPT WHERE TRUE
• SQL is *not* case-sensitive, except inside string constants.

• The syntax of SQL is format-free (newlines, whitespaces, *etc.* may be arbitrarily used).

Commonly found layout of SELECT-FROM-WHERE blocks

```
select  deptno, dname, loc
from    dept
```
Using Conditions (1)

To extract all data about the department in **DALLAS**

```sql
SELECT * FROM DEPT WHERE LOC = 'DALLAS'
```

- Result:

<table>
<thead>
<tr>
<th>DEPTNO</th>
<th>DNAME</th>
<th>LOC</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>RESEARCH</td>
<td>DALLAS</td>
</tr>
</tbody>
</table>

- String constants are enclosed in single quotes (`'`).

- Inside string constants, SQL is case-sensitive. The following will select 0 rows (empty result):

```sql
SELECT * FROM DEPT WHERE LOC = 'Dallas'
```
Print the name, job, and salary of all employees earning at least $2500

```
SELECT ENAME, JOB, SAL
FROM EMP
WHERE SAL >= 2500
```

• Result:

<table>
<thead>
<tr>
<th>ENAME</th>
<th>JOB</th>
<th>SAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>JONES</td>
<td>MANAGER</td>
<td>2975</td>
</tr>
<tr>
<td>BLAKE</td>
<td>MANAGER</td>
<td>2850</td>
</tr>
<tr>
<td>SCOTT</td>
<td>ANALYST</td>
<td>3000</td>
</tr>
<tr>
<td>KING</td>
<td>PRESIDENT</td>
<td>5000</td>
</tr>
<tr>
<td>FORD</td>
<td>ANALYST</td>
<td>3000</td>
</tr>
</tbody>
</table>
• SQL evaluates WHERE before SELECT:
The WHERE-clause may refer to columns which do not appear in the result.

Print the employee number and name of all managers

```sql
SELECT EMPNO, ENAME
FROM EMP
WHERE JOB = 'MANAGER'
```

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>ENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>7566</td>
<td>JONES</td>
</tr>
<tr>
<td>7698</td>
<td>BLAKE</td>
</tr>
<tr>
<td>7782</td>
<td>CLARK</td>
</tr>
</tbody>
</table>
SQL also provides an operator for text **pattern matching** allowing the use of wildcards:

Print the employee number and name of all managers

```
SELECT EMPNO, ENAME
FROM EMP
WHERE JOB LIKE 'MANA%'
```

▷ `%` matches any sequence of arbitrary characters,
▷ `_` (underscore) matches any single character.

Compare: UNIX shell globbing via `*` and `?`.
Pattern Matching (2)

- The SQL keyword LIKE needs to be used for pattern matching. The equals sign (=) tests for literal equality.

- The following is a legal SQL query but will return an empty result:

```
SELECT EMPNO, ENAME
FROM EMP
WHERE JOB = 'MANA%'
```
Arithmetic Expressions

- SQL provides the standard arithmetic operators.

**Print employee names earning less than $15,000 per year**

```
SELECT ENAME
FROM EMP
WHERE SAL < 15000 / 12
```

<table>
<thead>
<tr>
<th>ENAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMITH</td>
</tr>
<tr>
<td>ADAMS</td>
</tr>
<tr>
<td>JAMES</td>
</tr>
</tbody>
</table>

- The predicate `SAL * 12 < 15000` is equivalent (column names act like variable identifiers in programming languages).
Print the yearly salary of all managers

```
SELECT ENAME, SAL * 12
FROM EMP
WHERE JOB = 'MANAGER'
```

<table>
<thead>
<tr>
<th>ENAME</th>
<th>SAL * 12</th>
</tr>
</thead>
<tbody>
<tr>
<td>JONES</td>
<td>35700</td>
</tr>
<tr>
<td>BLAKE</td>
<td>34200</td>
</tr>
<tr>
<td>CLARK</td>
<td>29400</td>
</tr>
</tbody>
</table>

• To rename the second result column:

```
SELECT ENAME, SAL * 12 [AS] YEARLY_SALARY ...
```
Logical Connectives (1)

- The Boolean operators AND, OR, NOT and parentheses () may be used to construct more complex conditions.

```sql
SELECT ENAME, SAL
FROM EMP
WHERE JOB = 'MANAGER' OR JOB = 'PRESIDENT'
```

- The query would not work as expected with AND instead of OR.
Logical Connectives (2)

- Without parentheses, AND binds stronger than OR (and NOT binds stronger than AND).

Print name, salary of all well-paid managers and presidents

```
SELECT  ENAME, SAL
FROM    EMP
WHERE   JOB = 'MANAGER' OR JOB = 'PRESIDENT'
        AND SAL >= 3000
```

- The system will parse the condition as

```
WHERE   JOB = 'MANAGER'
OR      (JOB = 'PRESIDENT' AND SAL >= 3000)
```
Removing Duplicate Rows

- In general, queries can produce duplicate rows.

**List all jobs**

```sql
SELECT JOB FROM EMP
```

- The DBMS processes this query by a loop over table EMP and extracts the job of every employee. The same job name will be extracted multiple times (and then printed by the SQL console).

- **Duplicate row elimination** may be requested by adding the keyword DISTINCT after SELECT:

**List all distinct jobs**

```sql
SELECT DISTINCT JOB FROM EMP
```
The row ordering emitted by a SQL query is not predictable, unless an explicit request for sorting is added.

Print employees names and salary, alphabetically ordered by employee name

```sql
SELECT ENAME, SAL
FROM EMP
ORDER BY ENAME
```

Some SQL implementations implement the ORDER BY-clause on the SQL console level only: the row printing order is changed.
• The **ORDER BY**-clause permits multiple sorting criteria (useful only if one or more columns contain duplicate entries).

**Print employees who earn $2000 at least, ordered by department number and descending salaries**

```
SELECT DEPTNO, ENAME, SAL
FROM EMP
WHERE SAL >= 2000
ORDER BY DEPTNO, SAL DESC
```

• SQL orders lexicographically (here: first by DEPTNO, then by SAL).

• Sort order is ascending (**ASC**) by default.
Outlook: Joining Tables

- SQL allows to combine data from different tables.

**Print employees in the RESEARCH department**

```
SELECT ENAME
FROM EMP, DEPT
WHERE EMP.DEPTNO = DEPT.DEPTNO
AND DNAME = 'RESEARCH'
```

- Conceptually, SQL evaluates the WHERE-predicate for every combination of rows from both tables (cross product).

- Since column name DEPTNO appears in both tables, disambiguate the column reference by prefixing the table name ("dot notation").
## SQL Quiz (1)

### Table EMP

<table>
<thead>

</tbody>
</table>
SQL Quiz (2)

• Formulate the following queries in SQL:

Who has employee KING as direct supervisor?

Who has a salary between $1000 and $2000 (inclusive)?
Print name and salary and order the result by names.
Which employee names consist of exactly four characters?

Print name, salary, department of all employees who work in department 10 or 30 and earn less than $1500.
| Which jobs occur in which departments? |
Overview

1. The Relational Model, Example Database
2. Simple SQL Queries
3. Historical Remarks
The relational model (RM) was proposed by Edgar F. Codd (1970). It was the first data model that was theoretically defined prior to implementation. Codd won the Turing Prize in 1981.

First implementations (1967):
- **System R** (IBM)
- **Ingres** (Mike Stonebraker, UC Berkeley)

• **Much simpler** than earlier data models.
  One core concept: *finite relation* (set of tuples).

• Easily understandable, even for non-specialists:
  Relations correspond to tables.

• The theoretical model fits well with common implementation techniques:
  A relation is an abstraction of a *file of records*.

• The relational model features **set-oriented operation**. In earlier models, record-to-record navigation was explicit.
Reasons for Success (2)

- **Declarative query language.**

  A SQL query expresses the format and conditions that resulting tuples need to respect. The RDBMS contains a **query optimizer** that derives an efficient query evaluation plan (*i.e.*, an imperative program that evaluates the query) from this declarative specification. In earlier models, programmers had to explicitly think about the use of indexes and many more details.

- **The relational model has a solid theoretical foundation.**

  It is tightly connected to **first-order logic**.
Standards

  This was late as there were already several SQL systems on the market. The standard was the “smallest common denominator”, containing only the features common to existing implementations.

- Extension to foreign keys etc. in 1989 (SQL-89).

  This version is also called SQL-1. All commercial implementations today support SQL-89, but also features significant extensions.

  Standard defines three levels, “entry”, “intermediate”, “full.” Oracle 8.0, SQL Server 7.0 have entry level conformance.
Future

  
  SQL-99 is a preliminary version of the SQL-3 standard. Until 12/2000, the volumes 1–5 and 10 appeared (2355 pages; the SQL-2 standard, which is not completely implemented yet had 587 pages).

- Some features in the upcoming SQL-3:
  
  ▶️ User-defined data type constructors:
    
    - LIST, SET, ROW to structure column values
  
  ▶️ OO features (e.g., inheritance, subtables).
  
  ▶️ Recursive queries.
